

Identifiability class		
param	method	why
κ	first stage	ecDNA→EGFR slope, recorded per cell
β	2SLS (all)	VEGF: continuous per-cell readout
δ	2SLS (all)	migration: continuous per-cell readout
α	$\kappa_{\text{hyp}}=0$	division rate: inter-division intervals, T_{base} known
γ	—	apoptosis 5e-5/hr → no deaths → no survival selection

β , δ are deterministic per-cell phenotypes → read off the snapshot. α is a dynamic rate, identified only where EGFR is exactly reconstructable from ecDNA ($\kappa_{\text{hyp}}=0$). γ leaves no footprint because apoptosis is negligible — a design parameter, not a fit target.
